CLAIM FOR PRIORITY AND SUBMISSION OF DOCUMENTS

Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Dear Sir:

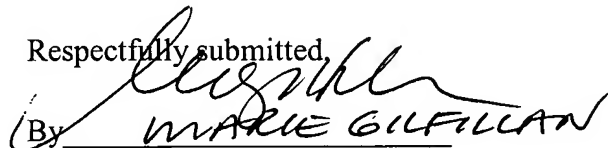

Applicant hereby claims priority under 35 U.S.C. 119 based on the following prior foreign application filed in the following foreign country on the date indicated:

<u>Country</u>	<u>Application No.</u>	<u>Date</u>
European Patent Office	EP 02 394 113.1	December 6, 2002

In support of this claim, a certified copy of the said original foreign application is filed herewith.

Dated: March 12, 2004

Respectfully submitted,

By

Antenna Switching Circuit

This invention relates to a switching circuit for use at the antenna of a multiband mobile cellular handset to select
5 between the TX and RX modes of the bands.

Multiband GSM-based mobile cellular handsets generally include a number of circuits for the TX and RX of the different bands of the handset. To select between the TX and RX modes of the
10 various RF bands, a switching circuit is usually employed at the antenna of the handset. The function of the switching circuit is to electrically connect the antenna of the cellular handset to the TX or RX circuit of the band which is in use at a given time, and to simultaneously isolate all other sections
15 of the handset from the antenna. This switching circuit is often incorporated into a single module, and this switching module is sometimes referred to as an antenna switch module (ASM). In addition to the switching function described above, the ASM may include low pass filters at the TX ports to filter
20 out unwanted harmonics from the TX signals.

A dual band cellular handset is normally designed to operate on a low band and on a high band. For example, handsets designed to operate within Europe generally are capable of
25 transmitting and receiving on the EGSM and DCS bands. The frequencies of operation of the TX and RX of the EGSM and DCS bands are listed in Table 1. It can be seen that the TX and RX frequencies of the EGSM band are centred around 920 MHz (low band), whereas the TX and RX frequencies of the DCS band
30 are centred around 1800 MHz (high band). A dual band ASM, for use in such a dual band cellular handset, facilitates switching of a single antenna between a TX low band input, a TX high band input, an RX low band output and an RX high band output. Consequently, a conventional dual band ASM has 5

ports: TX low band port, TX high band port, RX low band port, RX high band port, and antenna port.

Cellular System	TX Frequency Range	RX Frequency Range
AGSM	824-849 MHz	869-894 MHz
EGSM	880-915 MHz	925-960 MHz
DCS	1710-1785 MHz	1805-1880 MHz
PCS	1850-1910 MHz	1930-1990 MHz
W-CDMA	1920-1980 MHz	2110-2170 MHz

Table 1.

European Patent Application EP 0 921 642 discloses a conventional dual band ASM employing a diplexer at the antenna to separate the low band and the high band and further
 10 employing a pair of SP2T PIN switches to select between the TX and RX in each band. The ASM described in EP 0 921 642 also includes low pass filters at each of the two TX inputs.

It is an object of this invention to provide an improved
 15 antenna switching circuit which avoids the need for a diplexer at the antenna to separate the low band and the high band.

This object is met by the invention described by claim 1.

20 An embodiment of the invention provides a dual band ASM which represents a significant departure from the conventional topologies of dual band PIN switched ASMs as exemplified by EP 0 921 642. The embodiment has only 4 ports: TX low band port, TX high band port, RX port, and antenna port. It is
 25 based around a dual band SP3T PIN switch which can alternately connect the antenna port to the TX low band port, the TX high band port or the RX port. The various switching states are implemented using two control voltages.

The absence of a diplexer in the TX and RX signal paths results in a significant reduction in the insertion loss of the ASM. In addition, this absence improves the VSWR (Voltage
5 Standing Wave Ratio) at the various ports of the ASM.

The embodiment can be modified so that there are a pair of RX ports for cellular handset applications requiring an ASM with a low band RX port and a high band RX port. This modification
10 can be achieved by the inclusion of a conventional diplexer at the RX output. In this case the benefits of reduced loss, and reduced VSWR, apply to the TX ports only.

The TX high band frequency range, i.e. the frequency range of signals entering the TX high band port, may be that of a
15 single cellular high frequency band, e.g. the DCS band, or that of a combination of cellular high frequency bands, e.g. the DCS and PCS bands. Similarly, the TX low band frequency range, i.e. the frequency range of signals entering the TX low
20 band port, may be that of a single cellular low frequency band, e.g. the EGSM band, or that of a combination of cellular low frequency bands, e.g. the EGSM and AGSM bands.

Embodiments of the invention will now be described, by way of
25 example, with reference to the accompanying drawings, in which:

Fig. 1 shows a circuit diagram of an ASM according to an embodiment of the invention employing a SP3T silicon PIN diode
30 switch.

Fig. 2 shows a modified version the ASM of fig. 1, where low pass filters have been added at each of the TX inputs.

Fig. 3 shows the ASM of fig. 1 modified to include a pair of RX ports.

5 Fig. 4 shows a modification of the ASM of fig. 1 where each of the phase shifting transmission lines T_1 and T_2 have been replaced by a phase shifting network comprising of lumped components M_1 and M_2 .

10 Fig. 5 shows a dual band front end module (FEM) based on the ASM of fig. 1.

Fig. 6a shows a block diagram of a SAW triplexer.

15 Fig. 6b shows a circuit diagram of a possible implementation of the SAW triplexer of fig. 6a.

Fig. 7 shows a conventional diplexer.

20 Fig. 8 shows a low-band, high-band branching circuit which can be used in the impedance matching circuit of the SAW triplexer of fig. 6a.

Fig. 9 shows a circuit diagram of a PIN switched triple band FEM, based on the ASM of fig. 1 and the triplexer of fig. 6a.

25

Fig. 10a shows a block diagram of a SAW quadplexer.

Fig. 10b shows a possible implementation of the SAW quadplexer of fig. 10a.

30

Fig. 11 shows a circuit diagram of a quadband FEM, based on the ASM of fig. 1 and the quadplexer of fig. 10a.

Detailed description of the invention

Fig. 1 shows a block diagram of an ASM which employs a SP3T switch, comprising four silicon PIN diodes D_1 to D_4 , to selectively connect an antenna port 10 to a TX high band input port 12, a TX low band input port 14, or an RX output port 16 according to the combination of voltages $VC1$, $VC2$ applied at voltage input terminals 18, 20 respectively.

The TX high band port 12 is connected via a DC blocking capacitor C_B to the anode of D_2 , and the TX low band port 14 is similarly connected via a DC blocking capacitor C_B to the anode of D_1 . The antenna port 10 is connected at node A to the cathodes of both diodes D_1 and D_2 , at node B to the anode of D_3 via a first microstrip transmission line T_1 , and at node C to the anode of D_4 and the RX output port 16 via a further microstrip transmission line T_2 connected in series with the first transmission line T_1 . The cathode of D_3 is connected to ground via an LC resonator comprising L_1 and C_1 , and the cathode of D_4 is likewise connected to ground via an LC resonator comprising L_2 and C_2 . The inductances L_1 and L_2 may be specifically selected to optimise the electrical characteristics of the antenna switch, or may be constituted solely by the parasitic inductances of the respective diodes D_3 , D_4 .

The voltage input terminal 18 for $VC1$ is connected via a current regulating resistor R_I and a DC choke L_C to the anode of D_1 , and via a further DC choke L_C to the cathode of D_3 . A voltage smoothing capacitor C_s is added to the circuit, in a configuration such that one terminal of this capacitor is connected to the node where the resistor R_I and the two DC chokes L_C meet, and the other terminal is connected to ground.

The voltage input terminal 20 for VC2 is similarly connected via a current regulating resistor R_i and a DC choke L_c to the anode of D_2 , and via a further DC choke L_c to the cathode of D_4 . A second smoothing capacitor C_s is added to the circuit, so that one terminal of this second capacitor is connected to the node where the resistor R_i and the two DC chokes L_c meet, and the other terminal is connected to ground.

- 10 The TX low band of fig. 1 could be defined by the upper and lower edges of the frequencies of the AGSM cellular system, the EGSM cellular system, or any other cellular system with a frequency range around 1GHz, or any combination of these systems (see Table 1). The TX high band could be defined by
- 15 the upper and lower bounds of the frequencies of the DCS cellular system, the PCS cellular system, or any other cellular system with a frequency range around 2GHz, or any combination of these systems (see also Table 1).
- 20 In the present embodiment it is assumed that the TX low band is defined by the TX frequency range of the EGSM cellular system, and that the TX high band is defined by the TX frequency range of the DCS cellular system.
- 25 The ASM circuit of fig. 1 has three switching states (to allow SP3T operation). The switching logic for all three states is given in Table 2.

Switching State	ASM Function	VC1	VC2
1	RX	0	0
2	High Band TX	0	+V
3	Low Band TX	+V	0

Table 2.

Switching state 1.

In this state the voltages VC1 applied at 18 and VC2 applied
 5 at 20 are both zero. This results in a potential difference
 of zero volts across all four diodes D_1 - D_4 , so that all diodes
 are in the off state. A diode in the off state has a very
 high impedance, hence, in this state, the two TX ports 12 and
 14 are isolated from the circuit, and the two resonators (one
 10 comprising L_1 and C_1 and the other comprising L_2 and C_2) leading
 to ground from nodes B and C are also isolated from the
 circuit.

Consequently, in switching state 1, a signal entering the ASM
 15 of fig. 1 at the antenna port 10 will pass from the antenna
 port 10 to node A, and from node A, along transmission lines T_1
 and T_2 , to the RX output port 16.

Switching State 2

20

In this state, the voltage VC2 applied at 20 is high and the
 voltage VC1 applied at 18 is zero, so that diodes D_1 and D_4 are
 in the off state and diodes D_2 and D_3 are in the on state. A
 diode in the on state has a very low impedance, hence, in this
 25 state, the TX high band port 12 is connected directly to node
 A via the very low impedance of the switched on diode D_2 .
 Conversely, since diode D_1 is switched off, the impedance of
 the circuit path from node A to the TX low band port 14 is
 very high, and hence the TX low band port is isolated from
 30 node A. Along the circuit path from node A to the RX port 16,
 diode D_3 is switched on, connecting node B to ground via the
 series LC resonator comprising L_1 and C_1 . This resonator is
 tuned to have a resonance at the centre of the high band TX
 frequency range (1747.5MHz for DCS), and therefore within the

range of the DCS TX frequencies the impedance to ground at node B is almost zero (i.e. a short circuit). The short circuit at node B is connected to one end of the transmission line T_1 , the other end of the line T_1 being connected to node

5 A. Transmission line T_1 is constructed to have an electrical length of 90 degrees at the centre of the high band TX frequency range (1747.5MHz). A transmission line with an electrical length of 90 degrees at a particular frequency is often referred to as a quarter wave transmission line, and the
10 phase of the reflection coefficient at one end of a quarter wave transmission line is rotated through π radians at the other end. For example, a short circuit, which has a reflection co-efficient of -1, will have a reflection co-efficient of +1 when measured from the far end of a quarter
15 wave transmission line and conversely, an open circuit, which has a reflection co-efficient of +1, will have a reflection co-efficient of -1 when measured from the far end of a quarter wave transmission line. Hence, at frequencies near 1747.5MHz the short circuit at node B (which has a reflection co-
20 efficient of -1) appears like an open circuit at node A (which has a reflection co-efficient of +1), so that at these frequencies the path from node A to the RX port 16 is electrically equivalent to an open circuit.

25 To summarise, in switching state 2, the branch of the ASM circuit leading from node A to the high band input 12 has a very low impedance, whereas two of the branches connected to node A are open circuit (or have a very high impedance): the branch leading to the RX port 16 and the branch leading to the
30 TX low band port 14. Consequently, signals in the range 1710-1785 MHz coming from the TX high band port 12 will pass via diode D_2 and node A to the antenna port 10.

Switching State 3

In this state, the voltage VC1 applied at 18 is high and the voltage VC2 applied at 20 is zero, so that diodes D₂ and D₃ are in the off state and diodes D₁ and D₄ are in the on state. Since diode D₂ is switched off, the impedance of the circuit path from node A to the TX high band port 14 is very high, and hence the TX high band port is isolated from node A. However the TX low band port 14 is connected directly to node A via the very low impedance of the switched-on diode D₁. Along the circuit path from node A to the RX port 16, since diode D₃ is in the off state, the resonator, comprising L₁ and C₁, which connects diode D₃ to ground is isolated from node B. However, diode D₄ is switched on, so node C is connected to ground via the LC resonator comprising L₂ and C₂. This resonator is tuned to have a resonance at the centre of the low band TX frequency range (897.5MHz), and therefore near this frequency, the impedance to ground at node C is almost zero (i.e. a short circuit). The short circuit at node C is at one end of the pair of transmission lines T₁ and T₂ which are connected in series. Since diode D₃ is switched off in this state, the pair of transmission lines T₁ and T₂ can be treated like a single transmission line, with an electrical length which is equal to the sum of the lengths of both lines. As stated above, T₁ is constructed so that it has an electrical length of 90 degrees at the centre of the high band TX frequency range (1747.5MHz); this corresponds to an electrical length of approximately 46 degrees at the centre of the low band frequency range (897.5MHz). Accordingly, T₂ is designed so that it has an electrical length of approximately 44 degrees at the centre of the low band frequency range (i.e. so that the transmission lines T₁ and T₂ have a combined electrical length of 90 degrees at 897.5MHz). The other end of this pair of transmission lines is connected to node A. As described above, a

transmission line with an electrical length of 90 degrees has the effect of rotating the phase of the reflection coefficient at one end of the line through π radians at the other end. Hence, at frequencies around 897.5MHz the short circuit at node C appears like an open circuit at node A, so that at these frequencies, the path from node A to the RX port 16 is electrically equivalent to an open circuit.

To summarise, in switching state 3, the branch of the ASM circuit leading from node A to the low band input 14 has a very low impedance, whereas two of the branches connected to node A are open circuit (or have a very high impedance): the branch leading to the RX port 16 and the branch leading to the TX high band port 14. Consequently, signals in the range 880-915 MHz coming from the TX low band port 14 will pass via diode D_1 and node A to the antenna port 10.

The primary difference between the conventional ASM disclosed in EP 0 921 642 and the novel ASM of fig. 1 is that the conventional ASM is divided into a low band section and a high band section by placing a diplexer at the antenna. The absence of a conventional diplexer at the antenna of the ASM of fig. 1 reduces the insertion loss of the ASM. The reduction in insertion loss is due to the fact that there are less components in the paths of TX and RX signals which enter the ASM. The insertion loss of a conventional diplexer is typically in the order of 0.5dB at the low band and 0.75dB at the high band. The absence of a diplexer at the antenna port also considerably improves the VSWR of the ASM, which is of paramount importance in the TX path, since a high VSWR results in a large signal being reflected back into the power amplifier of the handset which has a detrimental effect on the RF performance of the cellular handset.

Another difference between the ASM of fig. 1 and the conventional ASM of EP 0 921 642 is that there is only a single RX port for the ASM of fig. 1, whereas the ASM of EP 0 921 642 has two RX ports - low band RX and high band RX.

5

Fig. 2 shows the novel ASM of fig. 1 modified to include low pass filters at the TX low band input and at the TX high band input, which may be required to filter out unwanted harmonics present in the TX signals entering the TX ports of the ASM.

10

For applications where a pair of RX ports are required, the ASM of fig. 1 can be modified to suit the requirements by the inclusion of a conventional diplexer at node C, as shown in fig. 3. Inclusion of a diplexer at the RX port 16 of the ASM of fig. 1 provides RX low and RX high band ports 16', 16" respectively. Although this modification increases the insertion loss of the ASM along the RX paths, it has no effect on the insertion loss of the ASM along the TX paths. Similarly, this modification has no effect on the VSWR at the TX ports and at the antenna port when the ASM is in either of the TX modes. Consequently, it can be seen that the ASM of fig. 1 can be configured to give exactly the same functionality as the conventional ASM of EP 0 921 642, but with the additional benefit of lower insertion loss in the TX paths and improved VSWR in the TX paths.

25

It has been stated herein that in switching state 2, the purpose of the transmission line T_1 in figs. 1-3 is to transform the short circuit at node B, which results from the switched on diode D_3 connected in series with L_1 and C_1 , so that this short circuit appears as an open circuit at node A. Similarly it has been stated that the purpose of the transmission line T_2 is so that the combined effect of T_1 and T_2 is to transform the short circuit at node C, resulting from

30

the switched on diode D_4 connected in series with L_2 and C_2 , so that this short circuit appears as an open circuit at node A.

Accordingly, the transmission lines T_1 and T_2 can individually
5 be replaced by any electrical circuit which has the effect of adding the appropriate phase shift at the TX low band, and the appropriate phase shift at the TX high band.

Fig 4 shows a modification of the ASM of fig. 1, where the
10 phase shifting transmission lines T_1 and T_2 , have been replaced with circuits M_1 and M_2 each comprising a respective pi-type LC network which includes a single series inductor buffered on either side by a shunt capacitor. The inductor and capacitors in the circuit M_1 are chosen so that M_1 gives rise to the same
15 electrical phase shift as transmission line T_1 ; whereas the inductor and capacitors in the circuit M_2 are chosen so that the circuits M_1 and M_2 together give rise to the same electrical phase shift as the serially connected transmission lines T_1 and T_2 .

20 Typically, all passive components such as transmission lines, matching circuits, and LC elements required to implement embodiments of the invention are implemented within and/or on the surface of a multi-layer substrate such a Low Temperature
25 Co-Fired Ceramic (LTCC) substrate.

Application to Dual Band Front End Module

A front end module (FEM) is an ASM which includes the RX
30 filters that are normally located external to the ASM. The RX filters employed are usually of the surface acoustic wave (SAW) type due to their small size and low insertion loss. SAW filters have the additional benefit of being capable of providing unbalanced to balanced conversion, which is useful

in cases where the RX input of the cellular handset comprises a pair of balanced terminals. The ASM of fig. 2 can be converted into a dual band FEM by the addition of a pair of RX SAW filters 24 and 26 at the outputs 16', 16'' of the diplexer 22 as depicted in fig. 5.

Application to Triple Band Front End Module

In recent times, there has been an increasing demand for triple band cellular handsets, which can operate on the EGSM, DCS and PCS bands (Table 1).

For triple band FEM, two TX ports are usually sufficient, as it is common for triple band cellular handsets to include only two power amplifiers, one for the EGSM TX, and one for the DCS and PCS TX. However separate RX ports are usually required for each band. So a triple band FEM generally includes 6 ports: TX low band port, TX high band port, three separate RX ports, and an antenna port.

An FEM covering the EGSM, DCS and PCS bands can be constructed from a conventional dual-band ASM as follows: by adjusting the TX high band section of the ASM so that it is optimised for TX signals in a range extending from the lower edge of the DCS TX and the upper edge of the PCS TX band (i.e. 1710 to 1910MHz); by the addition of a single EGSM SAW filter at the low band RX output; and by the addition of a DCS/PCS SAW duplexer at the high band RX output - see US Patent Application US2002/0032038.

To construct an FEM covering the EGSM, DCS and PCS bands using the ASM of fig. 1, the TX section of the ASM of fig. 1 must be adjusted as follows: the transmission line T_1 is adjusted so that it has an electrical length of 90 degrees for signals

midway between the lower edge of the DCS TX and the upper edge of the PCS TX band (i.e. 1810MHz); transmission line T_2 is re-adjusted so that the combined electrical length of T_1 and T_2 is 90 degrees for signals in the centre of the EGSM TX band (897.5MHz); the LC resonator comprising L_1 and C_1 is adjusted so that its resonant frequency is equal to 1810MHz.

Similarly the RX section of the ASM of fig. 1 must be modified to include three bandpass filters, one for each of the EGSM, DCS and PCS bands. However, the ASM shown in fig. 1 has only a single RX port, so the method outlined in US Patent Application US2002/0032038 cannot be used here.

To convert the RX section of the ASM of fig. 1 for triple band FEM functionality, a circuit is required which has a single input, which includes three outputs, and which further includes three RX bandpass filters such that the outputs of each of the three bandpass filters are connected to the outputs of the said circuit. This circuit must further be designed so that electrical signals at frequencies within the pass bands of any one of the bandpass filters which are applied to the input of the circuit will pass directly to the corresponding output of the circuit. Preferably the three bandpass filters are SAW filters and in such case this circuit will be referred to as a SAW triplexer herein.

A block diagram of a SAW triplexer is shown in fig. 6a, wherein three balanced output SAW filters 30, 32 and 34 are connected to node C via an impedance matching circuit 36 to provide three RX ports 16A, 16B and 16C with balanced outputs, one for each band. The impedance matching circuit 36 is designed so that when the three balanced outputs of the SAW triplexer are optimally terminated, the impedance to ground from node C along the circuit paths through any two of the SAW

filters 30-34 is very high compared with the impedance to ground along the circuit path through the other SAW filter at frequencies within the passband of that filter.

5 A possible implementation of the SAW triplexer of fig. 6a is shown in fig. 6b. This circuit includes a primary impedance matching sub-circuit 38 which is connected to node C, and a secondary impedance matching sub-circuit 40 which is connected to node D. The circuit also includes the three balanced
10 output bandpass SAW filters: one SAW filter 30 with a pass band which coincides with the EGSM cellular system, one SAW filter 32 with a pass band which coincides with the DCS cellular system, and one SAW filter 34 with a pass band which coincides with the PCS cellular system.

15

The function of the primary sub-circuit 38 (an example of which will be described below) is the isolation of the high band SAW filters from node C at low band frequencies, and the simultaneous isolation of the low band SAW filter from node C
20 at frequencies in the high band.

The secondary sub-circuit 40 comprises a length of transmission line T_3 connected to the input of the PCS SAW filter 34, and an LC network 42 connected to the input of the
25 DCS SAW filter 32. The length of line T_3 at the input of the PCS filter 34 has the effect of raising the impedance of the path from node D to the PCS output to a very high value at frequencies within the DCS band. However, the transmission line T_3 has no effect on the response of the PCS filter at
30 frequencies within the PCS band. Similarly, the LC network 42 at the input of the DCS filter 32 has the effect of raising the impedance of the path from node D to the DCS output to a very high value at frequencies within the PCS band, but has no effect on the response of the DCS filter within the DCS band.

Thus it can be seen that the secondary sub-circuit 40, which is connected to node D, together with the DCS and PCS SAW filters 32 and 34, achieves the functionality of a duplexer, so that electrical signals at frequencies within the DCS pass band at node D will pass directly to the DCS output of the triplexer, and electrical signals at frequencies within the PCS pass band at node D will pass directly to the PCS output of the triplexer.

A number of other embodiments of the secondary sub-circuit 40 exist in order that the secondary sub-circuit 40 together with the SAW filters 32 and 34 achieve the functionality of a DCS / PCS duplexer. A second embodiment would involve replacing transmission line T_3 with a matching circuit comprising of discrete components in the same manner that the transmission lines T_1 and T_2 in figs 1-3 can be replaced by LC matching circuits M_1 and M_2 as shown in fig. 4 above. A third embodiment would involve replacing the LC network 42 with a further transmission line, though for this embodiment, the new transmission line would preferably be connected in parallel with filter 42, so that one end of the transmission line was connected directly to ground.

The primary impedance matching sub-circuit 38, which is connected to node C of the SAW triplexer of fig. 6b can be implemented by a conventional diplexer such as that shown in fig. 7. A conventional diplexer includes three ports: a low band port, which is connected to one side of the circuit; a high band port, which is connected to the other side of the circuit; and a third port, which is connected to a point inside the circuit (denoted by node C in fig. 7). The component values of the diplexer are chosen so that when all of the ports of the diplexer are optimally terminated, the response of the diplexer, measured from node C to the low band

port is that of a low pass filter, and the response of the diplexer, measured from node C to the high band port is that of a high pass filter. Hence, the use of a conventional diplexer, such as that shown in fig. 7, for the primary sub-circuit 38 in the SAW triplexer of fig. 6b, achieves the desired result i.e. the isolation of the high band SAW filters from node C at low band frequencies, and the simultaneous isolation of the low band SAW filter from node C at frequencies in the high band.

Despite fulfilling the isolation requirements of the primary sub-circuit 38 of fig. 6b, the filtering effects introduced by a conventional diplexer are not a necessary requirement of the primary sub-circuit 38.

Fig. 8 shows an alternative circuit for the primary sub-circuit 38 of fig. 6b, which may be used in place of the conventional diplexer to isolate the high band and low band SAW filters. The circuit of fig. 8 is a branching circuit which comprises a pair of tuned circuits: a parallel tuned circuit 44, comprising L_p and C_p , and a series tuned circuit 46, comprising L_s and C_s . These tuned circuits are connected together at node C. The values of the inductance and capacitance in the parallel tuned circuit 44 are chosen so that together with the input impedance of the optimally terminated low band SAW filter 30 they form a resonant circuit with a resonant frequency which is midway between the lower edge of the DCS RX band and the upper edge of the PCS RX band (i.e. 1897.5MHz). Similarly the values of the inductance and the capacitance in the series tuned circuit 46 are chosen so that together with the input impedance of the secondary sub-circuit 40, and the optimally terminated high band SAW filters 32 and 34, they form a series resonant circuit with a resonant

frequency which is midway between the lower edge of the DCS RX band and the upper edge of the PCS RX band. For optimum isolation, the inductances and capacitances in both resonant circuits are chosen so that the Q of the parallel resonant circuit is equal to the Q of the series resonant circuit.

For the branching circuit of fig. 8, the values of the inductances and capacitances are calculated using equations 1a and 1b:

$$L_s = \frac{QZ}{\omega_{HB}} \quad C_s = \frac{1}{\omega_{HB} QZ} \quad \text{Equation 1a}$$

$$L_p = \frac{Z}{\omega_{HB} Q} \quad C_p = \frac{Q}{\omega_{HB} Z} \quad \text{Equation 1b}$$

where Z is the input impedance of the optimally terminated SAW filters within their respective pass bands, ω_{HB} is the frequency midway between the lower edge of the DCS RX band and the upper edge of the PCS RX band, and Q is the quality factor of the series and parallel resonators. For best results the Q in equations 1a and 1b should be in the range of 1 to 2.

The circuit of fig. 8 has the benefit of reduced complexity compared with the conventional diplexer of fig. 7. The circuit of fig. 8 additionally requires no connections to ground, thereby eliminating the need for via holes in the substrate of the triplexer, which would normally be required if the first sub-circuit 38 comprised a conventional diplexer such as that depicted in fig. 7.

It should be noted that the description of the triplexer described above is based on a circuit which employs three balanced output SAW filters. However, the triplexer could

employ three unbalanced output SAW filters, and one or more of the SAW filters could be replaced by another type of RF filter, such as a dielectric resonator filter; a film bulk acoustic resonator filter, such as that described in US patents US6462631 or US6215375; or a multi-layer filter implemented by discrete inductors and capacitors fabricated in an LTCC substrate.

A triple band FEM for the EGSM, DCS and PCS bands, implemented using the SAW triplexer of fig. 6a and the ASM of fig. 1 is shown in fig. 9. Dividing the FEM into two separate structures (an ASM and a SAW triplexer) enables a modular design approach, because the two structures are substantially independent of each other.

Application to Quad Band Front End Module

A further option for multi-band GSM-based mobile cellular handsets is that the handset be capable of transmitting and receiving on any one of four bands. For example, a quad band handset could be designed to operate on the AGSM, EGSM, DCS and PCS bands (Table 1).

A quad band FEM can be realised using the SP3T switching circuit of fig. 1, in a similar fashion to the method outlined above for constructing a triple band FEM using the ASM of fig. 1.

As with the triple band FEM described above, a quad band FEM covering the AGSM, EGSM, DCS and PCS bands requires only two TX inputs for the four bands - low band and high band. In this case, the low band TX input is optimised for frequencies ranging from the lower edge of the AGSM TX band to the upper edge of the EGSM TX band, and the high band TX input is

optimised for frequencies ranging from the lower edge of the DCS TX band to the upper edge of the PCS TX band.

To convert the RX section of the ASM of fig. 1 for quad band
5 FEM functionality, a circuit is required which has a single
input, which includes four outputs, and which further includes
four RX bandpass filters such that the outputs of each of the
four bandpass filters are connected to the outputs of the said
circuit. This circuit must further be designed so that
10 electrical signals at frequencies within the pass bands of any
one of the four bandpass filters which are applied to the
input of the circuit will pass directly to the corresponding
output of the circuit. Preferably the four bandpass filters
are SAW filters and in such case this circuit will be referred
15 to as a SAW quadplexer herein.

A block diagram of a SAW quadplexer is shown in fig. 10a,
wherein four balanced output SAW filters 52, 54 56 and 58 are
connected to node C via an impedance matching circuit 50 to
20 provide four RX ports 16A, 16B, 16C and 16D with balanced
outputs, one for each band. The impedance matching circuit 50
is designed so that when the four balanced outputs of the SAW
quadplexer are optimally terminated, the impedance to ground
from node C along the circuit paths through any three of the
25 SAW filters 52-58 is very high compared with the impedance to
ground along the circuit path through the other SAW filter at
frequencies within the passband of that filter.

A possible implementation of the quadplexer of fig. 10a is
30 shown in fig. 10b.. This circuit comprises a primary impedance
matching sub-circuit 58 and a pair of secondary impedance
matching sub-circuits 60 and 62. The function of the primary
impedance matching circuit 58 is the blocking of the high band
SAW filters from node C at low band frequencies, and the

simultaneous blocking of the low band SAW filter from node C at frequencies in the high band. As with the SAW triplexer of fig. 6a and 6b, the primary impedance matching circuit 58 could be constituted by a conventional diplexer, such as that of fig. 7, or a branching circuit such as that of fig. 8. Since the two high band SAW filters 56 and 58 of fig. 10b have the same passbands of the high band SAW filters 32 and 34 of fig. 6b, the second impedance matching circuit 60 of fig. 10b could be realised by an identical circuit to that of the secondary impedance matching circuit 40 of fig. 6b - i.e. a DCS/PCS SAW duplexer. Similarly, the secondary impedance matching circuit 62 of fig. 10b is designed so that together with the low band SAW filters 52 and 54, it constitutes an AGSM/EGSM SAW duplexer.

A quad band FEM, implemented using the SAW quadplexer of fig. 10a and the dual-band SP3T ASM of fig. 1, is shown in fig. 11. As above, the quad band FEM of fig. 11 comprises two separate circuits, an ASM and a SAW quadplexer. This structure facilitates a modular design approach, as the two structures are substantially independent of each other.

This specification has described a novel ASM, which is based around a dual band SP3T PIN diode switch, and which has 4 ports: an antenna port, a TX low band port, a TX high band port and an RX port. This ASM does not require a diplexer to separate the TX low band and TX high bands. It can be used in a dual band cellular handset to connect an antenna to a TX low band output, a TX high band output, and an RX input. The disclosed ASM has lower insertion loss than a conventional ASM, and the VSWR is also lower.

The ASM presented here can be configured to offer the same functionality of a conventional 5 port dual band ASM, by the

inclusion of a diplexer at the RX port. This configuration offers the benefit of lower insertion loss, and improved VSWR in both TX modes compared with a conventional dual band ASM.

5 This specification has further described a SAW triplexer circuit, which has a single input and three separate outputs and which can be used to direct electrical signals which fall within the pass band of any one of the SAW filters from the single input to the output of the relevant SAW filter. This
10 specification has furthermore described a front end module (FEM) which is constructed using the above dual band SP3T ASM and the above SAW triplexer. The FEM constructed in this fashion has very low insertion loss in both TX modes, in addition, the VSWR of this FEM is also very low in both TX
15 modes.

This specification has further described a SAW quadplexer circuit, which has a single input and four separate outputs and which can be used to direct electrical signals which fall
20 within the pass band of any one of the four SAW filters from the single input to the output of the relevant SAW filter. This specification has furthermore described a front end module (FEM) which is constructed using the above dual band SP3T ASM and the above SAW quadplexer. The quad band FEM
25 constructed in this fashion has very low insertion loss in both TX modes, in addition, the VSWR of this FEM is also very low in both TX modes.

The invention is not limited to the embodiments described
30 herein which may be modified or varied without departing from the scope of the invention.

Claims

1. A switching circuit for use at the antenna of a multiband mobile cellular handset, the circuit comprising an antenna
5 port, a TX low band port, a TX high band port and at least one RX port, the circuit further comprising a single pole, triple throw (SP3T) solid state voltage-controlled switch to selectively connect any one of the TX low band port, TX high band port and RX port to the antenna port.
10
2. A switching circuit as claimed in claim 1, wherein the SP3T switch comprises a plurality of single pole, single throw (SP1T) solid state switching devices.
- 15 3. A switching circuit as claimed in claim 2, wherein the SP1T switching devices are diodes.
4. A switching circuit as claimed in claim 2 or 3, wherein the antenna port is connected to the TX low band port via a
20 first SP1T device, to the TX high band port via a second SP1T device, and to the RX port via first and second frequency-dependent phase shifting elements connected in series, the circuit further including a first tuned circuit connected to the junction of the first and second frequency-dependent phase
25 shifting elements via a third SP1T device and a second tuned circuit connected to the end of the second frequency-dependent phase shifting element via a fourth SP1T device, the first tuned circuit being tuned to resonate substantially at the centre of the TX high band frequency range, the second tuned
30 circuit being tuned to resonate substantially at the centre of the TX low band frequency range, the first frequency-dependent phase shifting element corresponding to a quarter wavelength at frequencies in the TX high band frequency range, and the first and second frequency-dependent impedances in combination

corresponding to a quarter wavelength at frequencies in the TX low band frequency range.

5 5. A switching circuit as claimed in claim 4, wherein the first and second frequency-dependent phase shifting elements are first and second transmission lines respectively.

10 6. A switching circuit as claimed in claim 4, wherein the first and second frequency-dependent impedances are first and second LC networks.

15 7. A switching circuit as claimed in claim 4, 5 or 6 when dependent on claim 3, wherein the first diode has its anode connected to the antenna port and its cathode connected to the TX low band port, wherein the second diode has its anode connected to the antenna port and its cathode connected to the TX high band port, wherein the third diode has its anode connected to the junction of the first and second frequency-dependent impedances and its cathode connected to the first
20 tuned circuit, and wherein the fourth diode has its anode connected to the end of the second frequency-dependent impedance and its cathode connected to the second tuned circuit, the circuit further including a first voltage input terminal connected to the anode of the first diode and the
25 cathode of the third diode and a second voltage input terminal connected to the anode of the second diode and the cathode of the fourth diode.

30 8. A switching circuit as claimed in any preceding claim, wherein the at least one RX port comprises a plurality of different band RX ports derived from a common node of the circuit.

9. A switching circuit as claimed in claim 8, wherein the different band RX ports are each derived via a respective RF bandpass filter from the common node of the circuit.

5 10. A circuit for directing an RF input signal, appearing at a common node of said circuit and which may occupy any one of at least three mutually exclusive frequency bands, to a respective circuit output, the circuit including at least three RF bandpass filters each having a pass band
10 corresponding to a respective one of the frequency bands of the input signal, and an impedance matching circuit connecting said RF filters in parallel to said node and which is designed so that within the pass band of any given RF filter the impedance from said common node along the circuit paths
15 through the other RF filters is high compared to the impedance along the circuit path through the given RF filter.

11. A circuit as claimed in claim 10, wherein the RF filters are SAW filters.

20

12. A circuit as claimed in claim 10 or 11, wherein the RF filters have a balanced output.

13. A circuit as claimed in claim 10, 11 or 12, wherein the
25 impedance matching circuit comprises a first sub-circuit connected to said common node and having a low band output and a high band output, and a second sub-circuit connected to the high band output of the first sub-circuit and having first and second outputs for upper and lower bands of the high band
30 output.

14. A circuit as claimed in claim 13, wherein the low band output of the first sub-circuit comprises a parallel tuned

circuit and the high band output of the first sub-circuit comprises a series tuned circuit.

15. A circuit as claimed in claims 13 or 14, wherein one
5 output of the second sub-circuit comprises a transmission line
and the other output of the second sub-circuit comprises a
tuned circuit.

Abstract

A switching circuit for use at the antenna of a multiband mobile cellular handset comprises an antenna port 10, a TX low band port 14, a TX high band port 12 and at least one RX port 16. A single pole, triple throw solid state voltage-controlled switch made up of four PIN diodes D1 to D4 selectively connects any one of the TX low band port, TX high band port and RX port to the antenna port. No diplexer is used to separate the low and high band parts o the circuit.
